

### FEATURES

- Dual-channel, 10-Bit, 40 MSPS analog-to-digital converter
- Low power dissipation: 320 mW (typical)
- Internal track-and-hold
- Single +5 volt supply
- Tri-state, TTL/CMOS-compatible outputs
- Selectable +3 or +5 V logic I/O
- High ESD protection of 3,500 volts minimum

### APPLICATIONS

- Video set-top boxes
- Cellular base stations
- QPSK/QAM RF demodulation
- S-video digitizers
- Composite video digitizers
- Portable and handheld instrumentation
- Medical ultrasound
- Cable modems
- Video frame grabbers

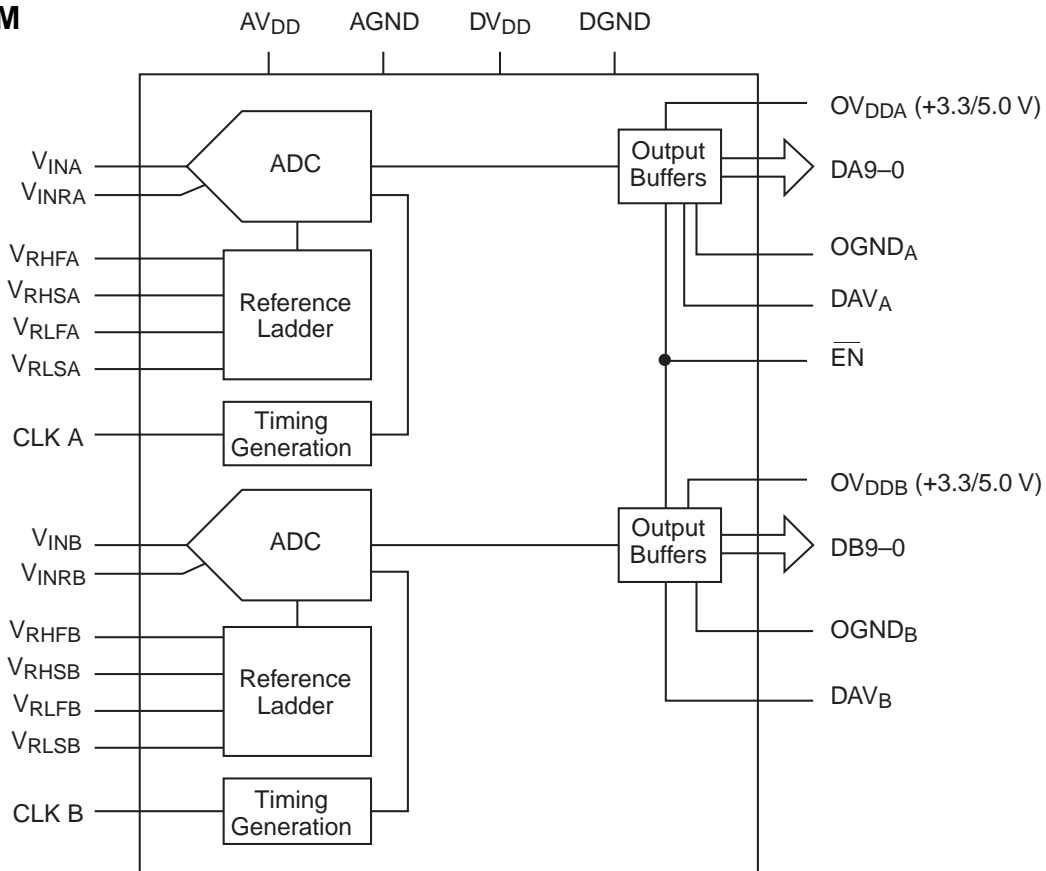

### GENERAL DESCRIPTION

The SPT7862 contains two separate 10-bit CMOS analog-to-digital converters that have sampling rates of up to 40 MSPS. Each device has its own separate clock and reference inputs so that they can be used independently in multichannel applications or can be driven from the same inputs for demanding quadrature demodulation and S-video applications. On-chip track-and-hold and advanced proprietary circuit design in a CMOS process technology provide very good dynamic performance.

The SPT7862 operates from a single +5 V supply. Digital data outputs are user selectable at +3 or +5 V. Output data format is straight binary.

The SPT7862 is available in a 64-lead TQFP package (10 x 10 mm) over the industrial temperature range of -40 °C to +85 °C.

### TEST LEVEL CODES

All electrical characteristics are subject to the following conditions:

All parameters having min/max specifications are guaranteed. The Test Level column indicates the specific device testing actually performed during production and Quality Assurance inspection. Any blank section in the data column indicates that the specification is not tested at the specified condition.

### TEST LEVEL

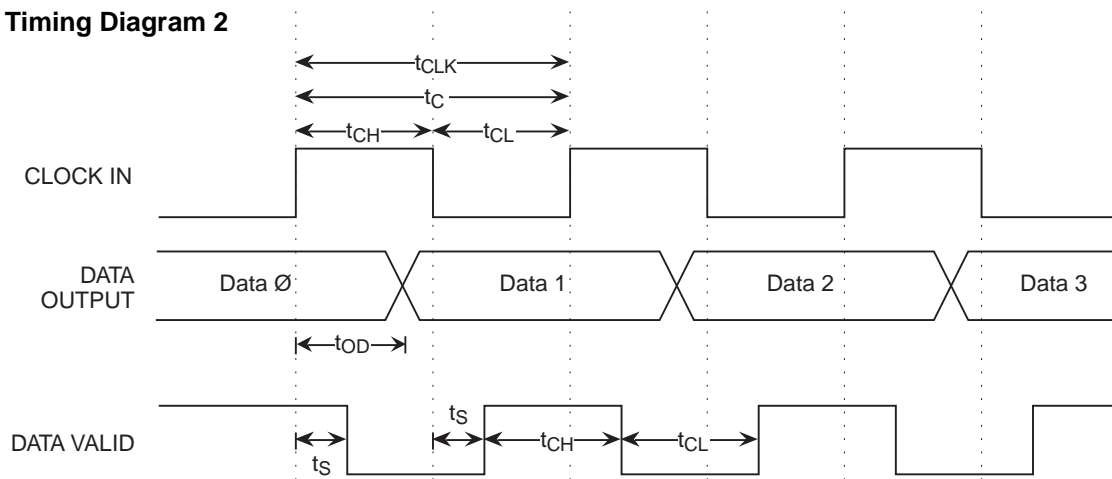

### TEST PROCEDURE

I	100% production tested at the specified temperature.
II	100% production tested at $T_A = 25$ °C, and sample tested at the specified temperatures.
III	QA sample tested only at the specified temperatures.
IV	Parameter is guaranteed (but not tested) by design and characterization data.
V	Parameter is a typical value for information purposes only.
VI	100% production tested at $T_A = 25$ °C. Parameter is guaranteed over specified temperature range.

## Spectral Response

**Figure 2 – Typical Interface Circuit**

**TYPICAL INTERFACE CIRCUIT**

Very few external components are required to achieve the stated device performance. Figure 2 shows the typical interface requirements when using the SPT7862 in normal circuit operation. The following sections provide descriptions of the major functions and outline critical performance criteria to consider for achieving the optimal device performance.

**POWER SUPPLIES AND GROUNDING**

Fairchild suggests that both the digital and the analog supply voltages on the SPT7862 be derived from a single analog supply as shown in figure 2. A separate digital supply should be used for all interface circuitry. Fairchild suggests using this power supply configuration to prevent a possible latch-up condition on power up.

**OPERATING DESCRIPTION**

The general architecture for the dual CMOS ADC is shown in the block diagram. Each ADC design contains 16 identical successive approximation (SAR) ADC sections (all operating in parallel), a 16-phase clock generator, an 11-bit 16:1 digital output multiplexer, correction logic, and a voltage reference generator which provides common reference levels for each ADC section.

The high sample rate is achieved by using multiple SAR ADC sections in parallel, each of which samples the input signal in sequence. Each SAR ADC uses 16 clock cycles to complete a conversion. The clock cycles are allocated as follows:

**Table II – Clock Cycles**

Clock	Operation
1	Reference zero sampling
2	Auto-zero comparison
3	Auto-calibrate comparison
4	Input sample
5–15	11-bit SAR conversion
16	Data transfer

The 16-phase clock, which is derived from the input clock, synchronizes these events. The timing signals for adjacent SAR ADC sections are shifted by one clock cycle so that the analog input is sampled on every cycle of the input clock by exactly one SAR ADC section. After 16 clock periods, the timing cycle repeats. The latency from analog input sample to the corresponding digital output is 12 clock cycles.

- Since only 16 comparators are used, a huge power savings is realized.
- The auto-zero operation is done using a closed loop system that uses multiple samples of the comparator's response to a reference zero.
- The auto-calibrate operation, which calibrates the gain of the MSB reference and the LSB reference, is also done with a closed loop system. Multiple samples of the gain error are integrated to produce a calibration voltage for each SAR ADC section.
- Capacitive displacement currents, which can induce sampling error, are minimized since only one comparator samples the input during a clock cycle.
- The total input capacitance is very low, since sections of the converter which are not sampling the signal are isolated from the input by transmission gates.

## VOLTAGE REFERENCE

The SPT7862 requires the use of a single external voltage reference for driving the high side of each reference ladder. Each ladder is totally independent and may operate at different voltage levels. The high side of the reference ladder must operate within a range of 3 V to 5 V. The lower side of each ladder is typically tied to AGND (0.0 V), but can be run up to 2.0 V with a second reference. The analog input voltage range will track the total voltage difference measured between the ladder sense lines,  $V_{RHS}$  and  $V_{RLS}$ .

Force and sense taps are provided to ensure accurate and stable setting of the upper and lower ladder sense line voltages across part-to-part and temperature variations. By using the configuration shown in figure 3, offset and gain errors of less than  $\pm 2$  LSB can be obtained.

In cases in which wider variations in offset and gain can be tolerated, the external reference can be tied directly to  $V_{RHF}$  and AGND can be tied directly to  $V_{RLF}$  as shown in figure 4. Decouple force and sense lines to AGND with a .01  $\mu$ F capacitor (chip cap preferred) to minimize high-frequency noise injection. If this simplified configuration is used, the following considerations should be taken into account:

The reference ladder circuit shown in figure 4 is a simplified representation of the actual reference ladder with force and sense taps shown. Due to the actual internal structure of the ladder, the voltage drop from  $V_{RHF}$  to  $V_{RHS}$  is not equivalent to the voltage drop from  $V_{RLF}$  to  $V_{RLS}$ .

**Figure 3 – Ladder Force/Sense Circuit for Each ADC**

**Figure 4 – Simplified Reference Ladder Drive Circuit Without Force/Sense Circuit**

Typically, the top side voltage drop for  $V_{RHF}$  to  $V_{RHS}$  will equal:

$$V_{RHF} - V_{RHS} = 2.25 \% \text{ of } (V_{RHF} - V_{RLF}) \text{ (typical),}$$

and the bottom side voltage drop for  $V_{RLS}$  to  $V_{RLF}$  will equal:

$$V_{RLS} - V_{RLF} = 1.9 \% \text{ of } (V_{RHF} - V_{RLF}) \text{ (typical).}$$

Figure 4 shows an example of expected voltage drops for a specific case.  $V_{REF}$  of 4.0 V is applied to  $V_{RHF}$  and  $V_{RLF}$  is tied to AGND. A 90 mV drop is seen at  $V_{RHS}$  ( $= 3.91$  V) and a 75 mV increase is seen at  $V_{RLS}$  ( $= 0.075$  V).

## ANALOG INPUT

$V_{INA}$  and  $V_{INB}$  are the analog inputs and  $V_{INRA}$  and  $V_{INRB}$  are the respective input returns. Each input return is typically tied to its respective low side reference ladder sense line. (See Figure 2.) The input voltage range is from  $V_{RLS}$  to  $V_{RHS}$  (typically 4.0 V) and will scale proportionally with respect to the voltage reference. (See the Voltage Reference section.)

The drive requirements for the analog inputs are very minimal, when compared to most other converters, due to the SPT7862's extremely low input capacitance of only 5 pF and a high input resistance in excess of 29 k $\Omega$ .

Each analog input should be protected through a series resistor and diode clamping circuit as shown in figure 5.

Figure 5 – Recommended Input Protection Circuit

D1 = D2 = Hewlett Packard HP5712 or equivalent

## CALIBRATION

The SPT7862 uses a user-transparent, auto-calibration scheme to ensure 10-bit accuracy over time and temperature. Gain and offset errors are continually adjusted to 10-bit accuracy during device operation.

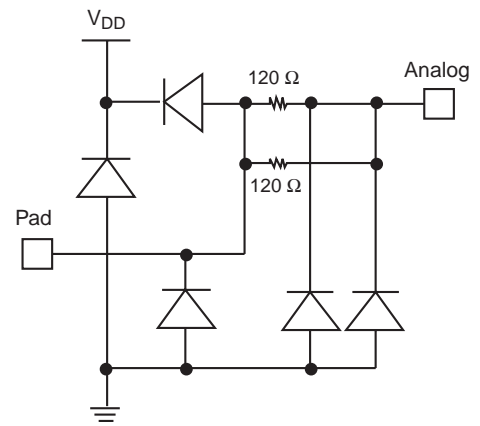

Upon power up, the SPT7862 begins its calibration algorithm. In order to achieve the calibration accuracy required, the offset and gain adjustment step size is a fraction of a 10-bit LSB. Since the calibration algorithm is an oversampling process, a minimum of 10,000 clock cycles are required. This results in a minimum calibration time upon power up of 250  $\mu$ sec (for a 40 MHz clock). Once calibrated, the SPT7862 remains calibrated over time and temperature.

Since the calibration cycles are initiated on the rising edge of the clock, the clock must be continuously applied for the SPT7862 to remain in calibration.

## INPUT PROTECTION

All I/O pads are protected with an on-chip protection circuit shown in figure 6. This circuit provides ESD robustness and prevents latch-up under severe discharge conditions without degrading analog transition times.

Figure 6 – On-Chip Protection Circuit

## CLOCK INPUT

Each ADC is driven independently from a single-ended TTL-input clock. Because the pipelined architecture operates on the rising edge of the clock input, each ADC can operate over a wide range of input clock duty cycles without degrading the dynamic performance.

## DIGITAL OUTPUTS

The digital outputs (DA9–0 and DB9–0) are driven by separate supplies ( $OV_{DDA}$  and  $OV_{DDB}$ ) ranging from +3 V to +5 V. This feature makes it possible to drive the SPT7862's TTL/CMOS-compatible outputs with the user's logic system supply. Each digital output supply may be driven independently. The format of the output data (D0–D9) is straight binary. (See Table III.) The outputs are latched on the rising edge of CLK. The  $\overline{EN}$  pin controls tri-stating of both data output ports. These outputs can be switched into a tri-state mode by bringing  $\overline{EN}$  high.

Table III – Output Data Information

ANALOG INPUT	OVERRANGE D10	OUTPUT CODE D9–D0
+F.S. + 1/2 LSB	1	11 1111 1111
+F.S. -1/2 LSB	0	11 1111 1110
+1/2 F.S.	0	00 0000 0000
+1/2 LSB	0	00 0000 0000
0.0 V	0	00 0000 0000

( $\emptyset$  indicates the flickering bit between logic 0 and 1)

## EVALUATION BOARD

The EB7862 evaluation board is available to aid designers in demonstrating the full performance of the SPT7862. This board includes a reference circuit, clock driver circuit, output data latches and an on-board reconstruction of the digital data. An application note describing the operation of this board as well as information on the testing of the SPT7862 is also available. Contact the factory for price and availability.
